(Received: April 2, 2008; Accepted: May 10, 2008)

# ABSTRACT

Fishes commonly consumed in Taiwan were purchased from four fish markets at seasonal intervals in 2006 in order to monitor the butyltin residues, including monobutyltin (MBT), dibutyltin (DBT), tributyltin (TBT), and tetrabutyltin (TeBT), in fishes caught along the west coast of Taiwan. Concentration of MBT, DBT, TBT, and TeBT in the muscle or the internal organ of these fishes were in the range of n.d.–949.2 ± 49.1, n.d.–56.2 ± 7.9, n.d.–70.8 ± 10.0, and n.d.–103.8 ± 76.9 ng/g (wet weight), respectively. Owing to the toxicological similarity between DBT and TBT, total concentrations of DBT plus TBT in the muscle or the internal organ were taken as the standard for the residue level of butyltins and they were found lower than the tolerable average residue level (TARL) of 175.4 ng/g (wet weight). Therefore, butyltin levels in fish from Taiwanese markets are not a matter of concern for public health.

Key words: butyltin compounds, Taiwan, fish markets, tolerable average residue level (TARL)

### **INTRODUCTION**

Over the last 40 years, organotin compounds have been extensively used as a pyrolysis stabilizer in the production of polyvinyl chloride (PVC), as a catalyst in the manufacture of polyurethane and silicone elastomer, as a stabilizer for improving resistance to ultraviolet radiation, and as a biocide to prevent fouling<sup>(1)</sup>. Therefore, they are present in PVC food packaging materials, polyurethane foams, antifouling paints, agrochemicals, and many other consumer products.

Through leaching from the antifouling paints used in boat, ship and other marine equipments, from the PVC products disposed into sanitary landfills, as well as from the runoff of agricultural fields, these compounds have been introduced into our estuarine and marine ecosystems. As organotin compounds are bioaccumulative<sup>(1)</sup>, tributyltin (TBT) and its breakdown products, monobutyltin (MBT) and dibutyltin (DBT) have been detected in a range of marine species including edible fish as well as invertebrates such as mollusks, crustaceans and cephalopods<sup>(1)</sup>.

Organotin compounds have harmful effects on a variety of non-targeted organisms, even at low nanomolar aqueous concentrations<sup>(1,2)</sup>. They are also suspected to have an endocrine disrupting ability in human. They may cause abnormalities in male reproductive systems<sup>(3,4,5)</sup>

and disrupt the critical function of human immune cells, particularly the killer cells which fight infection. Recent findings have revealed biologically significant levels of organotins in random human blood samples from the USA, and in human liver from Poland<sup>(6)</sup>.

Several investigations have shown that seafood is the primary source of human exposure to organotin compounds either in Asia or Europe<sup>(7,8,9)</sup>. Through the consumption of contaminated seafood, organotin compounds may enter the human body.

In Taiwan the use of organotin compounds in antifouling agents was restricted to boats under 25 m in length in 2003. However, butyltin compounds were still encountered in water and sediments<sup>(10,11)</sup>. This was attributed to TBT leached from antifouling paints from big commercial vessels (larger then 25 m in length) and/ or the persistence of TBT in sediments<sup>(12)</sup>.

Since many fishes consumed in Taiwan are harvested from the coast of Taiwan, it becomes necessary to monitor the levels of organotin compounds in fish commonly sold in markets in order to evaluate the extent of contamination after the controls of TBT, and to calculate the potential health risks to the public from consuming market-bought seafood. In this study, headspace solidphase microextraction (SPME) and gas chromatographyflame photometric detection (GC-FPD) analytical procedures were used to quantitatively determine the butyltin compounds in fishes from four fish markets in Taiwan.

# MATERIALS AND METHODS

# I. Sample Collection

Between March 2006 and November 2006, fish samples (about four to six fish species) were purchased from the fish markets in Keelung Bi-Sha (northern part of Taiwan), Hsinchu Nan-Liao (north central part of Taiwan), Taichung Wu-Gi (central part of Taiwan), and Pintung Dong-Gang (southern part of Taiwan), as shown in Figure 1, at seasonal intervals.

These fish samples included nine species of finfish (Trichiurus lepturus, Psenopsis anomala, Dentex tumifrons, Polydactylus microstomus, Acanthopagrus berda, Nematalosa nasus, Psettodes erumei, Pampus argenteus, and Pennahia argentata), and two species of shellfish (Babylonia formosae and Lunella coronata). They were all caught along the west coast of Taiwan. For each species three individual fish were purchased. The body length and body weight of the fishes were measured (Table 1). Subsamples were taken from the dorsal muscle of the finfish (about 20 g per subsample), the whole internal organ of the finfish (about 20 - 100 g per subsample), and the entire muscle of the shellfish (about 2 - 5 g per subsample) for analyses. Fish samples were frozen immediately after purchasing, and were transferred to the laboratory where they were stored at -20°C before analysis.

### II. Analytical Methods

Butyltin compounds in various tissues of fish samples were analyzed as described previously  $(^{11,13})$ . The removed muscle and the internal organ were freeze-dried and homogenized before analysis. The analytical procedure consisted of five steps: (i) acid digestion of the dry tissue (1 g) with 10 mL of HCl: tetrahydrofuran (1:11) and homogenized in a Tekmar tissumizer; (ii) extraction with 30 mL of tropolone-benzene (0.1 g/L) twice in a shaker for 40 min; the two organic extract were then combined; (iii) SPME procedure (13,14). In this procedure, solution containing 48.5 mL of artificial seawater, 1.5 mL of acetate buffer solution (pH 4.8), 50 µL aliquot of the fish extract, 250 µL of internal standard (tripropyltin chloride, 50 ng/L) and 100  $\mu$ L of 1% sodium tetraethylborate (NaBEt<sub>4</sub>, 98%; Strem Chemicals, France), were added into a bottle, and the fiber (100 µM polydimethylsiloxane; Supelco, USA) was then drawn into the bottle and situated approximately 1 cm above the aqueous surface. The bottle was incubated at 25°C for 50 min allowing for in situ NaBEt<sub>4</sub> derivatization and extraction to the fiber; (iv) the fiber retracted into the needle was immediately inserted into the GC injector for thermal desorption; (v) quantitative determination of butyltin compounds by Dani 1000 gas chromatographer equipped with a column (HP-5, 30  $m \times 0.25$  mm i.d.  $\times 0.25$  µM film thickness, Hewlett Packard, USA) and a flame photometric detector fitted with a 610 nm optical filter. The fiber was injected in splitless mode. The column temperature was programmed from 70°C (1-min holding time) to 190°C at 30°C/min and to 270°C (3-min holding time) at 15°C/min, and then to a final 290°C (1-min holding time) at 15°C/min. The injector temperature was 250°C, and the detector temperature was 290°C. All experiments were conducted in triplicate. Recoveries of MBT, DBT, TBT, and tetrabutyltin (TeBT) from spiked-in fish tissue samples (0.3 µg/g, N = 6) were 94.0-95.4%, 98.2-111%, 101-110%, and 76.4-88.0% (w/w), respectively. Slight difference in recovery was observed among different fish species. The method detection limit of MBT, DBT, TBT and TeBT were 3.2, 3.8, 3.8, and 3.6 ng/g (dry weight), respectively.

#### III. Crude Lipid Content Analysis

Water content of the dorsal muscle or the internal organ of the finfish and the shellfish was measured based on the weight difference between the wet weight and the freeze-dried weight of these tissues, while crude lipid content in these tissues was determined by continuous petroleum ether extraction in a Soxtec system<sup>(15)</sup>. All experiments were conducted in triplicate.

Wet-weight-based butyltin concentration was calculated from the dry weight based butyltin concentration and the average water content in these tissues.

#### **RESULTS AND DISCUSSION**

#### I. Biological Data of Samples

As shown in Table 1 the average body length and body weight of *T. lepturus*, *P. anomala*, *D. tumifrons*, *P. microstomus*, *A. berda*, *N. nasus*, *P. erumi*, *P. argenteus*, *P. argentata*, *B. formosae* and *L. coronata* used in this study were in the range from 1.8 to 85.0 cm and 6 to 765 g, respectively (as show in Table 2-6).

Water content in the dorsal muscle ranged from 55.0 to 85.2% (w/w), as shown in Table 2-6, while the water content in the internal organs from 45.7 to 90.5% (w/w). Crude lipid content in the dorsal muscle of these fishes were in the range from 0.2 to 13.7% (w/w) and the crude lipid content in the internal organs from 0.8 to 38.9% (w/w).

# II. Concentration of Butyltin Compounds in Fish Samples

Concentration of butyltin compounds in the fish samples collected from March 2006 to November 2006 are determined and shown in Table 2-6. Concentrations of TBT and the total concentration of butyltin compounds (BTs) in the muscle were in the range from n.d. to 70.8  $\pm$  10.0 ng/g and n.d. to 953.7  $\pm$  49.7 ng/g (wet weight), respectively (as show in Table 2-6). The highest concentrations of TBT (70.8  $\pm$  10.0 ng/g) and BTs (953.7  $\pm$  49.7 ng/g) were found in the muscle of *D. tumifrons* and *T.* 

# lepturus, respectively.

Concentrations of TBT and BTs in the internal organs were in the range from n.d. to  $38.9 \pm 9.8$  ng/g and n.d. to  $632.8 \pm 76.0$  ng/g (wet weight), respectively (as show in Table 2-6). The highest concentrations of TBT ( $38.9 \pm 9.8$  ng/g) and BTs ( $632.8 \pm 76.0$  ng/g) in internal organs were found in *T. lepturus* and *P. anomala*, respectively.

Although the concentration of each butyltin compound varied greatly for different individuals, different species, and different seasons, MBT was prevalent in most of the muscle and internal organ samples determined. Concentrations of MBT and BTs in the muscle and the internal organs of T. lepturus, P. anomala, D. tumifrons and P. microstomus were significant different (p < 0.05, by ANOVA test) from different months. We also found the mean of concentrations of MBT and BTs were higher in fishes caught in June (325.9 and 328.2 ng/g) than in the other months (64.8 and 72.0 ng/g, March; 91.8 and 106.4 ng/g, September; 88.5 and 108.0 ng/g, November), but there was no clear seasonal trend for other fish species. Different from our results, Dong et al.<sup>(10)</sup> found that ponyfish Leiogenathus splendens collected from the west coast of Taiwan contained higher BTs in winter than in other seasons.

In this study we also found that in some cases, concentrations of TBT or BTs were higher in the muscle, but in other cases, the concentrations of TBT or BTs were higher in the internal organs of the fish. Suzuki et al.<sup>(16)</sup> reported higher concentration of BTs in the liver than in the muscle of yellowtail. When determining butyltin compounds in the skin, dorsal muscle, ventral muscle, dark muscle, and liver in cobia Rachycentron canadum raised in offshore aquaculture sites, the researchers found that in most cases the highest concentration of total butyltin residues was in the liver or skin, but in some cases the highest concentration was in the muscle tissue<sup>(11)</sup>. Several factors such as temperature, diet, or enzyme activity that result in degradation of TBT in the tissues, might cause variation in the butyltin concentration in different tissues of the fish<sup>(17,18)</sup>.

Concentrations of TBT and BTs in the muscle and the total length of *T. lepturus* (r = -0.249, r = 0.0141; N = 16), *P. anomala* (r = -0.443, r = 0.0714; N = 13), *D. tumi-frons* (r = 0.112, r = 0.188; N = 11), and *P. microstomus* (r = -0.244, r = 0.105; N = 11) were not related. Concentrations of TBT and BTs in the internal organs and the total length of *T. lepturus* (r = 0.289, r = 0.199; N = 16), *P. anomala* (r = 0.265, r = -0.0693; N = 13), *D. tumifrons* (r = 0.127, r = 0.347; N = 11), and *P. microstomus* (r = -0.132, r = 0.290; N = 11) were also not related either.

No correlation was observed between the concentrations of TBT and BTs, and the lipid content in the muscle of *T. lepturus* (r = -0.155, r = 0.128; N = 14), *P. anomala* (r = 0.163, r = 0.191; N = 11), *D. tumifrons* (r = 0.544, r = 0.208; N = 10), and *P. microstomus* (r = -0.149, r =0.101; N = 12). Neither was there a correlation observed Journal of Food and Drug Analysis, Vol. 16, No. 6, 2008

between the concentrations of TBT and BTs, and the lipid content in the internal organs of *T. lepturus* (r = 0.202, r = 0.157; N = 12), *P. anomala* (r = -0.237, r = 0.720; N = 10), *D. tumifrons* (r = -0.371, r = -0.179; N = 8), and *P. microstomus* (r = -0.079, r = 0.267; N = 10). Harino *et al.*<sup>(19)</sup> also found that the concentration of TBT in muscle was not related to the total length of the fishes. Neither correlation was observed between the concentration of TBT and the lipid content in the muscle of fish.

Kannan *et al.*<sup>(6,20)</sup> surveyed the butyltin residues in</sup> the muscle tissue of fishes collected from several local markets and seafood shops in Asia and Oceanic countries between 1990 and 1994, and found that the total butyltin residues in tilapia, milkfish, and seabream bought in Taiwan were 0.49, 0.96, and 18 ng/g wet weight. On the other hand, a recent study has shown that TBT and total butyltin residue levels in the liver, dorsal muscle, ventral muscle and dark muscle of cobia (R. canadum) aquacultured in the offshore of Taiwan were n.d.-1140 and n.d.-52745, 75-338 and 79-688, n.d.-497 and 82-1715, and 66–528 and 93–803 ng/g (wet weight), respectively<sup>(11)</sup>. Although the concentrations of each butyltin compound varied greatly among different fish species, the concentrations of TBT and the total butyltin residues in the muscle tissues and liver of aquacultured cobia were much higher than those of the nonfarmed fishes caught from the coastal area of Taiwan. Similar to our results, Sasaki et al.<sup>(21)</sup> and Ueno et al.<sup>(22)</sup> also found that the concentrations of TBT or total butyltin compounds were much higher in aquacultured fishes than in wild fishes.

Similar to the situation in Taiwan, in Italy, four years after the restrictions on the usage of organotins, DBT was detected in the range of 1-26 ng/g and 1-4 ng/ g wet weight, and TBT was detected in the range of 2-260 ng/g and 1-93 ng/g wet weight, respectively in both the farmed fishes and the free living fishes (including mussels)<sup>(23)</sup>. Six years after the ban on the use of TBT for all coastwise vessels and aquaculture facilities was enacted in Japan, the TBT concentration in the muscle of 11 species of fishes from the port of Osaka and Yodo River was detected to be in the range of 11-182 ng/g wet weight<sup>(19)</sup>. In the USA, six years after the controls on organotins were put into place in 1988, butyltin concentrations in fishes collected from the Gulf of Mexico during 1994 ranged between 158 and 289 ng/g wet weight. These results together with recent reports on the butyltin pollution in seawater and sediments<sup>(24,25,26)</sup> have shown that the sources of TBT contamination still remain worldwide, and that the partial ban on TBT usage was not sufficient to reduce the threat of butyltin compounds to human health.

#### III. Status of Food Safety

Seafood consumption is the main source of human dietary exposure to butyltin compounds. The toxicology of butyltin compounds in humans has not yet been

fully resolved<sup>(27)</sup>. On the basis of TBT's ability to reduce the immune function, Penninks<sup>(28)</sup> suggested a tolerable daily intake (TDI) for TBT of 0.25  $\mu$ g/kg body weight/ day. Various attempts have thus been made to determine whether the level of organotin intake by humans from eating marine food should be a cause for concern.

The tolerable average residue level (TARL) is defined as the level in seafood that is tolerable for the average consumer with an average body weight of 60 kg.

TARL= (TDI  $\times$  60 kg body weight)/Average daily seafood consumption

In Taiwan an average 85.5 g/day/person of seafood was consumed in  $1993-1996^{(29)}$ . Using this value, an estimated 175.4 ng/g (wet weight) of TARL for TBT in seafood was obtained.

Penninks<sup>(28)</sup> found that DBT is equipotent or more toxic than TBT for mammals. He suggested that for the determination of toxicity both DBT and TBT should be considered. Heidrich *et al.*<sup>(30)</sup> also reported that human placental aromatase activity is directly inhibited by TBT ( $IC_{50} = 6.2 \mu M$ ) or DBT but not by MBT and tetrabutyl-tin. Therefore, concentrations of DBT plus TBT in the muscle or the internal organ were taken while considering the residue level of butyltins.

Neither DBT nor TBT were detectable in 70% of the muscle and 87% of the internal organ of our samples. The highest concentrations of DBT plus TBT in the muscle and in the internal organs were found in D. tumifrons  $(103.8 \pm 18.6 \text{ ng/g} \text{ and } 118.5 \pm 81.1 \text{ ng/g}, \text{ respective-}$ ly) purchased in November. When the TBT concentration in seafood from markets in Asia, Australia, Europe, and North American were investigated, Keithly and his coworker<sup>(31)</sup> found that the TBT residues in marketable seafoods were consistent worldwide, averaging 185 ng/g dry weight. Considering the dry/wet ratio of fish muscle, TBT concentrations in seafood caught from the west coast of Taiwan were lower than those from other markets in the world. Concentration of DBT plus TBT in muscle and internal organs of all these tested fishes did not exceed the TARL value of 175.4 ng/g (wet weight). Based on our results, levels of DBT plus TBT observed in the muscle of fishes caught from the west coast of Taiwan were not matters of concern for human health.

#### ACKNOWLEDGEMENTS

This research was financially supported by the Administration of Agriculture of Taiwan, under grant number 95–Agric–9, 1, 2, –Fish–F1 (3).
